1. Neutron star mergers and kilonovae

2. Theoretical method

Atomic structure computation: HFR
Expansion opacity

3. Existing works

4. Results

Opacity sensitivity to atomic properties
Lanthanide and actinide expansion opacities
Actinide VS lanthanide opacities

5. Conclusion

- ▶ Detection of gravitational waves from neutron star merger GW170817 for the first time on August 17, 2017 (Abbott B.P. *et al.*, Phys. Rev. Lett. **119**, 161101, 2017)

- ▶ NSMs also produce an electromagnetic signal powered by the ejection of hot and radioactive matter: **kilonova (KN)**
- ▶ GW170817 EM counterpart also detected: **KN AT2017gfo**
- ▶ KNe thought to be responsible for heavy element production

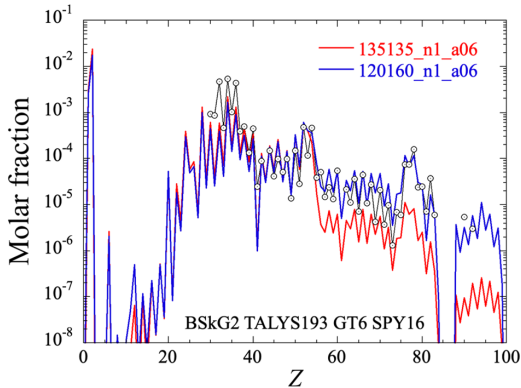

1. Neutron star mergers and kilonovae

- ▶ KN light curve modeling strongly depends on atomic opacities
- ▶ KN opacity dominated by millions of lines from f-shell elements (→ lanthanides + actinides) newly created by r-process

The image shows a periodic table with the following features:

- Title:** PERIODIC TABLE Atomic Properties of the Elements
- Source:** NIST National Institute of Standards and Technology, U.S. Department of Commerce, Physical Measurement Laboratory, www.nist.gov
- Content:** A grid of elements with their symbols, atomic numbers, and names. Each element cell contains detailed physical and chemical data.
- Legend:**
 - Solids (blue)
 - Liquids (orange)
 - Gases (green)
 - Artificially Prepared (red)
- Highlighted Area:** A red box encloses the lanthanide and actinide series, which are the f-shell elements mentioned in the text.

1. Neutron star mergers and kilonovae

(S. Goriely, O. Just, private communication)

⇒ Lanthanide and actinide contributions to the opacity are of paramount importance due to their large spectral density and abundances

1. Neutron star mergers and kilonovae

- ▶ Many studies are based on a simple but powerful one-zone approximation (e.g. Metzger 2019, Hotokezaka & Nakar 2020)
→ Ejecta = expanding homogeneous sphere with gray opacity
- ▶ Monte-Carlo approaches solve the radiative-transfer eqs very accurately using atomic-physics based opacities, but are computationally expensive and often assume analytic ejecta distributions (e.g. Kasen *et al.* 2017, Kawaguchi *et al.* 2019)
- ▶ Intermediary approach: truncated two-moment approximation (so-called M1 scheme), which assumes a local closure relation ("equation of state") for the radiation field (Just *et al.* 2022)
→ fills the gap between the two approaches above in terms of both accuracy and complexity

So far, the KN total opacity in Just *et al.* 2022's code is estimated using crude approx to atomic-physics based model, motivated by fits to bolometric KN light curves

$$\kappa(X_{\text{LA}}, T) = \kappa_{\text{LA}} \times \kappa_T$$

where the X_{LA} -dependent part is

$$\kappa_{\text{LA}} \equiv \begin{cases} 30 \text{ cm}^2 \text{ g}^{-1} (X_{\text{LA}}/10^{-1})^{0.1} & , X_{\text{LA}} > 10^{-1} , \\ 3 \text{ cm}^2 \text{ g}^{-1} (X_{\text{LA}}/10^{-3})^{0.5} & , 10^{-3} < X_{\text{LA}} < 10^{-1} , \\ 3 \text{ cm}^2 \text{ g}^{-1} (X_{\text{LA}}/10^{-3})^{0.3} & , 10^{-7} < X_{\text{LA}} < 10^{-3} , \\ 0.2 \text{ cm}^2 \text{ g}^{-1} & , X_{\text{LA}} < 10^{-7} , \end{cases}$$

(Just, Kullman, Goriely
et al., MNRAS **510**,
2820, 2022)

and the temperature-dependent part is

$$\kappa_T \equiv \begin{cases} 1 & , T > 2000 \text{ K} \\ \left(\frac{T}{2000 \text{ K}}\right)^5 & , T < 2000 \text{ K} . \end{cases}$$

X_{LA} : average lanthanide
+ actinide mass fraction

→ Realistic KN opacity would require big amounts of **reliable atomic data** (structure + radiative data for all transitions) for both **lanthanides and actinides**

1. Neutron star mergers and kilonovae

Kilonova: physical conditions

Temperature VS density
of the KN photosphere

Just and Goriely,
private communication

$$\Rightarrow 10^{-17} \text{ g}/\text{cm}^3 < \rho < 10^{-13} \text{ g}/\text{cm}^3$$

and

$$1000 \text{ K} < T < 10000 \text{ K}$$

Flörs, Silva, Deprince *et al.* 2023 (accepted)

\Rightarrow Only the first ionization stages (I – IV) of the elements are present in the KN ejecta

1. Neutron star mergers and kilonovae

Pseudo-relativistic Hartree-Fock Method

- ▶ Based on Schrödinger equation
- ▶ Orbitals obtained for each config. by solving the HF eqs (↪ variational principle to the config. average energy)
- ▶ Relativistic corrections added perturbatively

Advantages of HFR method:

- ▶ Calculation is relatively quick, even for a large number of configurations considered (↪ large number of transitions)
 - ▶ States from all the configurations are optimized
- ⇒ Suitable to compute physical properties as opacity which requires to consider large numbers of transitions (↪ lanthanides and actinides) all fairly well described

Expansion opacity:

$$\kappa_{\text{exp}}^{\text{bb}}(\lambda) = \frac{1}{\rho c t} \sum_l \frac{\lambda_l}{\Delta \lambda} (1 - e^{-\tau_l})$$

with the Sobolev optical depth:

$$\tau_l = \frac{\pi e^2}{m_e c} t n_l \lambda_l f_l$$

⇒ Radiative wavelength λ_l and oscillator strength f_l are needed to compute the expansion opacity (+ level population n_l)

(n_l is determined using Boltzmann and Saha equations)

- Recent studies for weakly-charged lanthanide opacities, e.g.:
 - ▶ Kasen *et al.* (2013) → Nd I – IV, Ce II – III using AUTOS
 - ▶ Gaigalas *et al.* (2019) → Nd II – Nd IV using GRASP
 - ▶ Gaigalas *et al.* (2020) → Er III using GRASP
 - ▶ Radžiūtė *et al.* (2020) → Pr II – Gd II using GRASP
 - ▶ Tanaka *et al.* (2020) → All lanthanides using HULLAC
 - ▶ Fontes *et al.* (2020) → All lanthanides using Los Alamos codes
 - ▶ Carvajal Gallego *et al.* (2021) → Ce II – IV using GRASP
 - ▶ Rynkun *et al.* (2022) → Ce IV using GRASP and HULLAC
 - ▶ Gaigalas *et al.* (2022) → Pr IV using GRASP
 - ▶ Silva *et al.* (2022) → Nd III using FAC
 - ▶ Flörs, Silva, Deprince *et al.* (2023, accepted)
↔ Nd II – III using FAC and HFR (this work)
- + Several works on moderately-charged lanthanides (early-phase kilonovae) from Carvajal Gallego *et al.* and Banerjee *et al.*

3. Existing works

- Only very few works focused on actinide opacities, e.g.:
 - ▶ Silva *et al.* (2022) → (Nd III and) U III using FAC
 - ▶ Fontes *et al.* (2023) → All actinides using Los Alamos codes
 - ▶ Deprince, Carvajal Gallego, Godefroid *et al.* (2023)
↪ U II – IV using HFR (sensitivity studies, this work)
 - ▶ Flörs, Silva, Deprince *et al.* (2023, accepted)
↪ (Nd II – III) and U II – III using FAC and HFR (this work)

Effect of the multiconfiguration model

Models for U III

- ▶ Silva *et al.* 2022 (FAC):

$$5f^4 + 5f^3\{6d+6f\} + 5f^3\{7s+7p+7d\} + 5f^3\{8s+8p\} \\ + 5f^2\{6d^2+6d7s\} \\ (10 \text{ configurations})$$

- ▶ Our work (HFR):

$$5f^4 + 5f^3\{6d+6f+6g\} + 5f^3\{7s+7p+7d+7f+7g\} \\ + 5f^3\{8s+8p+8d+8f+8g\} + 5f^3\{9s+9p+9d+9f+9g\} \\ + 5f^2\{6d^2+6d7s+6d7p+6d7d+7s^2+7s7p+7s7d\} \\ (26 \text{ configurations})$$

How are the computed opacities affected by the multiconfiguration model (by the number of config.) ? Convergence of the models?

Model convergence for U III

Convergence of the opacity while considering growing models
(more configurations added shell by shell)

Calibration procedure

Calibration procedure used in HFR: adjustment of the configuration average energies to the ones deduces from available energy levels

In both U II and U III, level inversion occurs in our computations between (namely) the ground state and one of the first excited states

→ Our calibration procedure solves this level inversion problem

- ▶ Is such an adjustment procedure worth it in order to compute opacities (at least in a first step)?

(Deprince, Carvajal Gallego, Godefroid *et al.* 2023)

Calibration procedure (U III)

Calibration procedure (U II)

Core-polarization effect

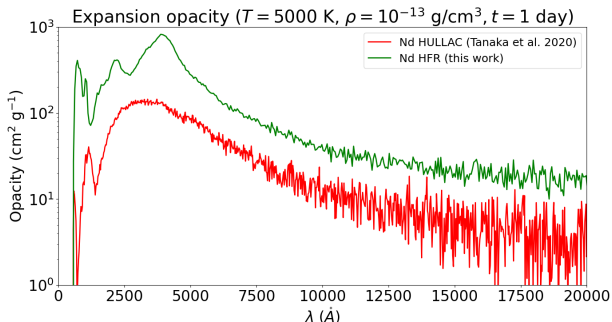

- ▶ HFR: not all the correlations are explicitly taken into account
→ Model = ionic core + config. involving valence electrons
- ▶ UMONS team (Atomic Physics and Astrophysics Unit) has modified Cowan's codes to include a core-polarization correction to the potential (Quinet *et al.*, MNRAS **307**, 934, 1999)
- ▶ Can be tricky to include for elements for which nf subshell is partially filled (ionic core not clearly defined)
- ▶ Is this effect worth being included in our opacity computations (in a first step)?

(Deprince, Carvajal Gallego, Godefroid *et al.* 2023)

Core-polarization effect (U II)

Importance of considering realistic partition functions (Nd opacity case)

Significant difference between our HFR opacity and the one computed by Tanaka *et al.* 2020 using HULLAC

- ▶ Atomic data → Importance of the multiconfiguration model!
(7 and 8 configs included for Nd II and Nd III in Tanaka *et al.*)

4. Results

a) Opacity sensitivity to atomic properties

Importance of considering realistic partition functions (Nd opacity case)

- Expansion opacity computation itself
 - In Tanaka *et al.* (2020) (as well as in Gaigalas *et al.* 2019), the partition function $U(T)$ is approximated to g_0 in the evaluation of level populations n_l ($\rightarrow \tau_l$):

$$n_l = \frac{g_l n}{U(T)} \exp(-E_l/kT)$$

$$\tau_l = \frac{\pi e^2}{m_e c} t n_l \lambda_l f_l$$

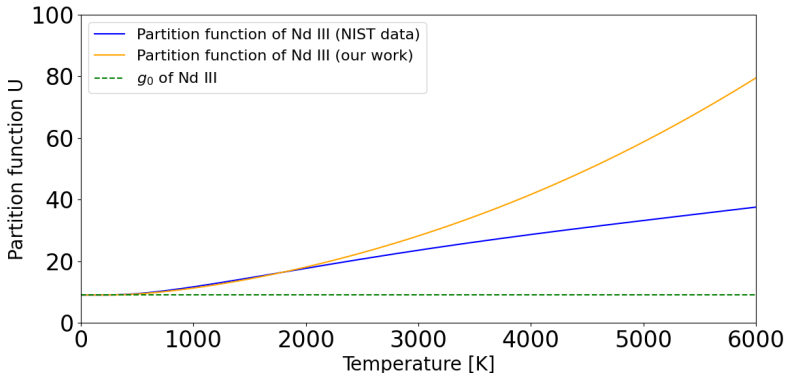

$$U(T) = \sum_{i=0}^{\infty} g_i \exp\left(-\frac{E_i - E_0}{kT}\right), \quad g_i = 2J_i + 1$$

4. Results

a) Opacity sensitivity to atomic properties

Partition Function of Nd III

For Nd III, for $T = 5000$ K, U is about 6 times greater than g_0 !

Carvajal Gallego, Deprince, Godefroid *et al.* 2023

+ *cf.* Carvajal Gallego *et al.*'s poster (moderately-charged lanthanides)

4. Results

a) Opacity sensitivity to atomic properties

Comparison with other works

GRASP: Gaigalas, Kato, Rynkun *et al.* (2019)

HULLAC: Tanaka, Kato, Gaigalas *et al.* (2020)

(Opacities recomputed using their atomic data $\rightarrow U(T)$ NOT approximated to g_0)

FAC + HFR (This work): Flörs, Silva, Deprince *et al.* (2023)

4. Results

b) Lanthanide and actinide expansion opacities

Comparison with other works

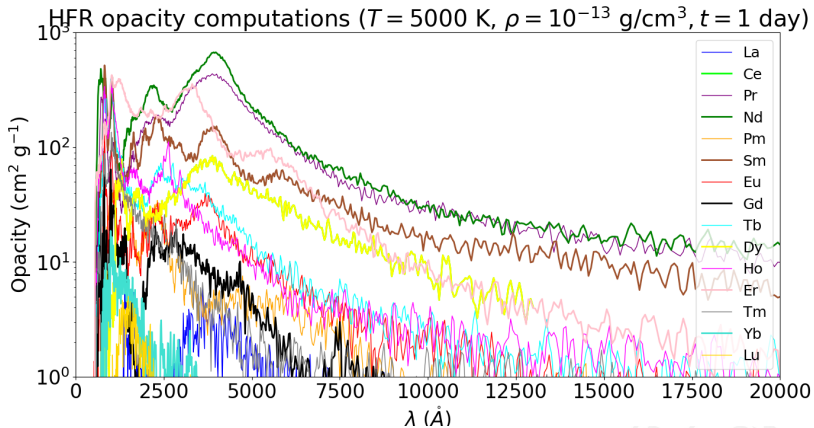

$$\kappa_{g,n}^{b-b} = \frac{1}{\rho_n c t_n} \frac{1}{\Delta \lambda_g} \sum_{i \in \Delta \lambda_g} \begin{cases} \lambda_i \tau_i, & \text{for binned,} \\ \lambda_i (1 - e^{-\tau_i}), & \text{for expansion.} \end{cases}$$

Fontes *et al.* (2020)
 \hookrightarrow Line-binned opacities
 (instead of expansion)

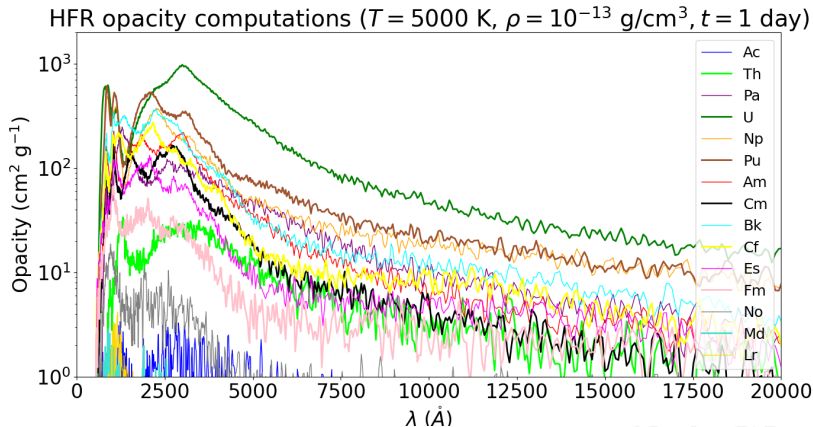

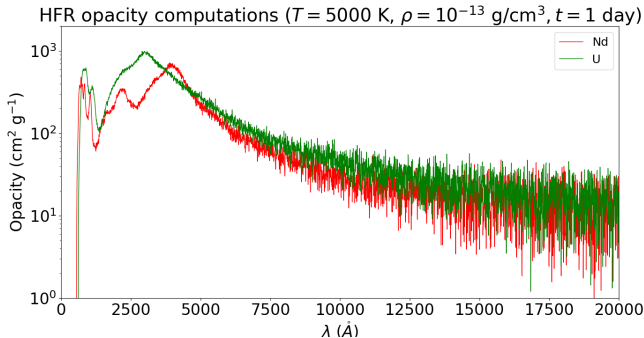

Flörs, Silva, Deprince *et al.* (2023)

Opacity of weakly-charged lanthanides

Opacity of weakly-charged actinides

⇒ U opacity at least
as large as Nd opacity

⇒ Importance of the actinide
opacities as well

4. Results

c) Actinide VS lanthanide opacities

Lanthanide and actinide Planck mean opacities

Conclusion

- ▶ Opacity computations needed to model kilonova light curves
 - ↪ Reliable atomic data for as many transitions as possible
 - Especially for lanthanides and actinides which are expected to dominate the KN opacity
- ▶ Lanthanides: several works exist but can be improved
- ▶ Actinides: very few works
 - Multiconfiguration model choice is of crucial importance
 - Partition functions fully-computed (not approximated to g_0)
- ▶ HFR expansion opacities computed for all weakly-charged lanthanides and actinides for a grid of T , ρ and time
- ▶ Opacity for U as large as for Nd or even greater
 - ⇒ Actinides can be as important as lanthanides concerning their contributions to the KN opacity

- ▶ Average the computed opacities with the expected elemental abundances for several NSM cases (nucleosynthesis simulations from S. Goriely, ULB) to infer the KN total opacity
- ▶ Implement the new atomic opacity data in kilonova light curve model (O. Just's code, Just *et al.* 2022)
- ▶ Try to improve atomic data (especially for the most contributing species)
⇒ Investigate impact on the computed opacities
- ▶ Exhaustive comparison with the opacities computed by other groups using other methods (GSI/Lisbon University, NIST-Los Alamos Lanthanide Opacity Database, Japan-Lithuania Opacity Database for Kilonova)
